

REMARKS/ARGUMENTS

Reconsideration of this application is respectfully requested in view of the foregoing amendments and discussion presented herein.

1. **Claim Interpretation.**

Clarification has been requested with respect to the claimed separator plate being "flexible or ridged". It appears that the term "ridged" is a typographical error in the application. The abstract, claims, and specification have been amended to recite "rigid" instead of "ridged". The Applicant appreciates the Examiner's thorough review.

Notably, a marked up specification and a substitute specification are enclosed herewith to facilitate correction of the typographical error in the application, along with a replacement abstract sheet.

2. **Rejections under 35 U.S.C. § 112, first paragraph.**

Claims 2-37 are rejected under 35 U.S.C. § 112, first paragraph, as failing to comply with the written description requirement. The Examiner states:

The claims as now amended recite that the edge portion of the separator plate of rolled, bent over, or rolled and/or crimped *over the sealed edge portions of said flexible membrane*. There is no clear support for this arrangement as recited in the amendment and therefore raises new matter. (emphasis in original)

Later in the Office Action, the Examiner states:

[I]n particular, the specification lacks sufficient description to support the amendment to claims 2 and 23 as to the separator being bent over or crimped *over the edge of said flexible membrane assembly*[.] (emphasis in original)

The Examiner is mistaken on this point. At the time of filing, part "c" of Claim 2 read as follows:

- c. a flexible seal, adhesive or gasket interposed between said single flexible or ridged separator plate and said flexible membrane electrode assembly, wherein said flexible seal, adhesive or gasket between said flexible or ridged separator plate and said flexible membrane electrode assembly comprises the fuel cell module, and wherein said flexible seal, adhesive or gasket is optionally an adhesive which encapsulates edge portions of said flexible or ridged separator plate and said flexible membrane electrode assembly and wherein said flexible seal, adhesive or gasket seals the edge portions of said flexible membrane assembly to prevent the release of reactants from the fuel cell, and where ***the edge portion of the flexible or ridged separator plate is secured by rolling, bending over, crimping over the edge or combinations thereof of the said flexible membrane assembly and the said flexible seal*** and pressed or crimped against the said flexible membrane assembly and the said flexible seal to prevent the release of reactants from the fuel cell[.] (emphasis added)

Thus, Claim 2, at the time of filing, specifically stated that the separator is *bent over or crimped over the edge of the flexible membrane assembly*.

Notably, the instant application describes and illustrates a number of techniques and configurations to "mechanically restrain[] the edge of the adhesives or gaskets in order to prevent release of reactants from the fuel cell." (Page 11, lines 15-18). Such techniques and configurations include "bending and crimping or hemming as shown in FIGS. 9A-9C ... [and] rolling the edges" of the bipolar separator plate. (Page 11, lines 19-22). In this regard, "[i]n order to support the sealing of the gasket and/or sealing adhesives 64, the edges of the flexible or rigid bipolar separator plate 61 can be [bent] over or rolled and/or crimped against the sealing [surface] of the membrane electrode assembly." (Page 11, lines 8-11). Figures 9A-9D are schematic representations of a thin metal bipolar separator plates before (Figure 9A) and after (Figure 9B) crimping or

rolling of the edges to support MEA 65—"without the MEA 65 ... for clarity." (Page 11, lines 12-13).¹

In sum, part "c" of amended Claim 2 recites:

the edge portion of the flexible or rigid bipolar separator plate is secured by bending over or crimping over the edge of said flexible membrane electrode assembly and said flexible seal to prevent the release of reactants from the fuel cell[.]

Claim 2, as filed, included the same language. Thus, this amendment does not constitute new matter and should be entered.

3. Drawings.

The Examiner believes that new Figures 10A-10D introduce new matter into the application. Specifically, the Examiner believes that "[t]he separator being bent over or crimped over the edge of said flexible membrane assembly and seal constitutes new matter which cannot be entered." As noted in the discussion hereinabove, this arrangement is not new matter.

Also, the Examiner has objected to the drawings because they do not show

¹ In the event that the Examiner is concerned as to the placement of the membrane electrode assembly (MEA 65) relative to bipolar separator plate 61 in new Figures 10A-10D, there should be no doubt that MEA 65 is disposed as depicted in Figures 10A-10D because this location is required to provide for the basic operation of the fuel cell. Indeed, this relative positioning is also clear from other embodiments (see, for example, Figures 6 and 8A-8D). Moreover, as noted above, Figures 9A-9D illustrate certain techniques of mechanically restraining the edge of the adhesives or gaskets in order to support sealing action of the gasket and/or sealing adhesives—"without the MEA 65 ... for clarity." (Page 11, lines 12-13). Were MEA 65 to be located differently than in new Figures 10A-10D, there would have been no need to omit MEA 65 in Figures 9A-9D "for clarity" purposes.

every feature specified in the claims. Specifically, the Examiner states "the separator being bent over, or rolled and/or crimped over the sealed edge portions of said flexible membrane assembly must be shown". Figures 10A-10D show this arrangement of elements.

It appears that the Examiner is requiring the Applicant to show an element that he considers to be new matter, and thus, both the structure as claimed and the new drawing figures that show this structure as in the claim have been rejected as new matter. However, the Examiner's kind attention is drawn to the fact that no new matter has been presented, either in the claims, noted hereinabove, or in the drawings.

According to MPEP 2163.04, "[i]nformation contained in any one of the specification, claims or drawings of the application as filed may be added to any other part of the application **without introducing new matter**" (emphasis added). As noted hereinabove, the wording of newly amended Claim 2 is the same wording that was present in original Claim 2 at the time of filing. This wording is part of the original disclosure and is not new matter, so including this arrangement in Figures 10A-10D is similarly not new matter.

Moreover, according to MPEP 608.01(I), "[i]f subject matter capable of illustration is originally claimed and it is not shown in the drawing, the claim is not rejected but applicant is required to add it to the drawing." In the original form of Claim 2, "*the edge portion of the flexible or [rigid] separator plate is secured by rolling, bending over, crimping over the edge or combinations thereof of the said flexible membrane assembly and the said flexible seal*". In response, the Applicant respectfully points out that new Figures 10A-10D specifically show the edge portion of the separator plate secured by bending over or crimping over the edge of the flexible membrane assembly and the flexible seal. This is no more than that arrangement specified in the original form of Claim 2.

Amended Claim 23 contains the same language, to wit: "the perimeter edge portion of the BSP is secured by bending over or crimping over the edge of the MEA".

This language is clearly supported by the language in the original form of Claim 2, and is not new matter.

Because the language in the current form of Claims 2 and 23 is not new matter, Figures 10A-10D, showing *"the edge portion of the flexible or rigid bipolar separator plate is secured by bending over or crimping over the edge of said flexible membrane electrode assembly and said flexible seal"*, do not contain new matter and should be entered.

4. Attorney Docket Number.

The Examiner's kind attention is directed to the docket number to be used for this application, ALT6089.04A.

5. Amendments Made Without Prejudice or Estoppel.

Notwithstanding the amendments made and accompanying traversing remarks provided above, Applicants have made these amendments in order to expedite allowance of the currently pending subject matter. However, Applicants do not acquiesce in the original ground for rejection with respect to the original form of these claims. These amendments have been made without any prejudice, waiver, or estoppel, and without forfeiture or dedication to the public, with respect to the original subject matter of the claims as originally filed or in their form immediately preceding these amendments. Applicants reserve the right to pursue the original scope of these claims in the future, such as through continuation practice, for example.

6. Conclusion.

Based on the foregoing, Applicants respectfully request that the various grounds for rejection in the Office Action be reconsidered and withdrawn with respect to the presently amended form of the claims, and that a Notice of Allowance be issued for the present Application to pass to issuance.

INTEGRATED AND MODULAR BSP/MEA/MANIFOLD PLATES FOR FUEL CELLS

BACKGROUND OF THE INVENTION

Related Applications

This application is a continuation-in-part of U.S. Serial No. 60/226,471, filed August 18, 2000 and U.S. Serial No. 60/249,662, filed November 17, 2000, and U.S. Serial No. 09/834,390, filed April 13, 2001 by Express Mail No.: EL700013365US, all of which are incorporated herein by reference in their entirety.

Field of the Invention

The present invention relates to electrochemical energy converters with a polymer electrolyte membrane (PEM), such as fuel cells or electrolyzer cells or stacks of such cells, wherein the individual cells are modular units which have integrated the bipolar separator plate (BSP), the membrane electrode assembly (MEA) and the reactant and coolant manifolds. These individual components are assembled into integrated modules and these modules, are tested individually for full functionality before being assembled into a complete fuel cell unit (stack) as individual components. In particular the several components of the integrated modular BSP/MEA/Manifolds (fuel cell module), i.e., the bipolar separator plate, membrane electrode assembly, separate diffusion layers (if used), gaskets (if used), manifolds, adhesives, and seals (if used) are manufactured as separate entities before being incorporated into a fuel cell module before being assembled in a complete fuel cell unit (stack). In a number of embodiments, these fuel cell components can be as large or as small as the end use requires.

Description of the Related Art

Electrochemical cells comprising polymer electrolyte membranes (PEM) may be operated as fuel cells wherein a fuel and an oxidizer are electrochemically converted at the cell electrodes to produce electrical power, or as electrolyzers wherein an external electrical current is passed between the cell electrodes, typically through water, resulting in generation of hydrogen and oxygen at the respective electrodes of the cells.

Fuel cells are energy conversion devices that use hydrogen, the most abundant fuel on earth, and oxygen, usually from the air, to create electricity through a chemical conversion process, without combustion and without harmful emissions. The voltage and current output depends on the number of cells in the stack, total active surface area and efficiency. The basic process, for a single cell, is shown in Figure 1.

Traditional fuel cell stacks 1, see Figure 2, are made of many individual cells 2, see Figure 3, which are stacked together. The ability to achieve the required gas and liquid sealing and to maintain intimate electrical contact has traditionally been accomplished with the use of relatively thick and heavy “end plates” (3, 4) with the fuel cell stack 5 held together by heavy tie-rods or bolts 6 and nuts 7 (or other fasteners) in a “filter-press” type of arrangement, see Figures 2 and 4. Disassembly and analysis of fuel cell stacks built by traditional and other methods reveals evidence of incomplete electrical contact between bipolar separator plates (BSPs) 8 and the membrane electrode assembly (MEAs) 9, which results in poor electrical conduction, lower cell performance, often along with evidence of gas and liquid leakage.

The traditional method of assembly of Proton Exchange Membrane (PEM) fuel cells requires several parallel and serial mechanical processes that must be accomplished simultaneously for each individual cell, see Figure 3.

1. The Membrane Electrode Assembly (MEA) 9 must be sealed to the Bipolar Separator Plates (BSPs) 8 at each plate/MEA interface, via a gasket such as 10A and 10B.
2. The fuel, oxidizer and coolant manifolds 11A and 11B are all required to be sealed at the same time during fabrication as the MEA is sealed to the BSP.
3. The BSPs 8 must be in intimate electrical contact with the electrode assembly 9, across its entire surface area, at all times for optimum performance.

As the traditional fuel cell stack 1 is assembled, each individual cell (layer) 2 must seal, manage gasses and liquid, produce power and conduct current. Each cell relies on all the other cells for these functions. Additionally, all seals and electrical contacts must be made concurrently at the time of assembly of the stack, see Figures 2 and 3.

The assembly of a traditional PEM cell stack which comprises a plurality of PEM cells each having many separate gaskets which must be fitted to or formed on the various components is labor-intensive, costly and in a manner generally unsuited to high volume manufacture due to the multitude of parts and number of assembly steps required.

With the conventional PEM stack design 1, see Figure 2, it is problematic to remove and repair an individual cell 2 (see Figure 3) or to identify or test which cell or cells in the stack may require repair due to leakage or performance problems. In many cases the entire stack assembly is required to be disassembled. The disassembly of a stack consisting of multiple cells, each comprising separate cell components can be very costly as in many instances, after the removal of one cell, the gaskets of the remaining cells may need to be replaced before the stack can be reassembled and operated. Additionally, the potential for damage to

the MEA is very high. Upon reassembly, there is no assurance of the performance or of a leak tight condition. This is a very time consuming and therefore costly process.

Some patents of interest are listed below.

R.G. Spear, et al. in U.S. Patent 5,683,828, assigned to H Power Corporation disclose metal platelet fuel cells production and operation methods.

R.G. Spear, et al. in U.S. Patent 5,858,567, assigned to H Power Corporation disclose fuel cells employing integrated fluid management platelet technology.

R.G. Spear, et al. in U.S. Patent 5,863,671, assigned to H Power 25 Corporation disclose plastic platelet fuel cells employing integrated fluid management.

R.G. Spear, et al. in U.S. Patent 6,051,331 assigned to H Power Corporation disclose fuel cell platelet separators having coordinate features.

These four U.S. patents to Spear et al. describe conventional fuel cell assembly.

W.A. Fuglevand, et al. in U.S. Patent 6,030,718, assigned to Avista Corporation disclose a proton exchange membrane fuel cell power system.

D.G Epp, et al. in U.S. Patent 5,176,966 disclose a fuel cell membrane electrode and a seal assembly.

W.J. Fletcher, et al. in U.S. Patent 5,470,671 disclose an electrochemical fuel cell which employs ambient air as both oxidant and coolant.

W.D. Ernest, et al. in U.S. Patent 5,945,232 disclose a PEM-type fuel cell assembly having multiple parallel fuel cell sub-stacks employing shared fluid plate assemblies and shared membrane electrode assemblies.

R.A. Mercuri, et al. in U.S. Patent 5,976,727 disclose an electrically conductive seal for fuel cell components.

R.D. Breault, et al. in U.S. Patent 6,020,083 disclose a membrane electrode assembly for a PEM fuel cell.

R.H. Burton, et al. in U.S. Patent 6,057,054 disclose a membrane electrode assembly for an electrochemical fuel cell and a method of making an improved membrane electrode assembly.

J.A. Ronne, et al. in U.S. Patent 6,066,409 disclose an electrochemical fuel cell stack with improved reactant manifolding and sealing.

O. Schmidt et al. in U.S. Patent 6,080,503 disclose polymer electrolyte membrane fuel cells and stacks with adhesively bonded layers.

Other art of general interest includes, for example: U.S. Patent 5,338,621; European Patent 446,680; U.S. Patent 5,328,779; U.S. Patent 5,084,364; U.S. Patent 4,548,675 and U.S. Patent 4,445,994.

All of the references, patents, patent applications, standards, etc. cited in this application are incorporated by reference in their entirety.

With reference to Figure 3 and Claims 1 and 2 of United States Patent 6,080,503 which is incorporated herein by reference, the adhesive bonding agent used is for bonding "a first separator plate" and "a second separator plate" to a membrane electrode assembly", in the current embodiment a single separator plate is bonded to a single MEA and to manifolds which are external to the membrane assembly with no through passages holing the membrane. This embodiment forms a fuel cell module (assembly).

It is apparent from the above discussion that existing fuel cell technology can be significantly improved using modular components and in the assembly of the multiple fuel cell unit (stack). This invention concerns an improved, integrated

and modular BSP/MEA/Manifold assembly, which facilitates single cell (module) leak and performance testing prior to assembly. It also eliminates gaskets between adjacent BSP and simplifies assembly. The present invention of modular, integrated units provides such improvements for a fuel cell. Specifically incorporated by reference in its entirety is pending U. S. Provisional Patent Serial Number 60/226,471, filed August 18, 2000 and pending U.S. Serial Number 09/ 834,390, filed April 13, 2000 by Express Mail Certificate Number EL700013365US.

SUMMARY OF THE INVENTION

This invention concerns an improved, integrated and modular BSP/MEA/Manifold, which facilitates single cell (module) assembly as well as composed leak and performance testing of the modules prior to stack assembly. It also eliminates inter BSP gaskets and seals and simplifies cell assembly as well as stack assembly.

In addition, thin, flexible or ~~ridged~~ rigid BSPs are used to manage reactants and maintain separation of the fuel and oxygen (or air); provide structural support for the MEAs and provide electrical contact and conductance. They also provide for the decoupling of the electrical contacts and for the sealing from the fuel cell stack assembly, thus reducing mechanical difficulties in manufacture and assembly, conducting current more efficiently and eliminating serial sealing problems. The present invention of modular, integrated units provides such improvements for a fuel cell.

In particular, the present fuel cell comprises:

1. a single flexible or ~~ridged~~ rigid bipolar separator plate;
2. a flexible membrane electrode assembly;

3. a flexible bond or seal interposed between said flexible or ~~ridged~~ rigid separator plate and said flexible membrane electrode assembly wherein said flexible bond or seal may be or may not be an adhesive bond or seal which encapsulates edge portions of said flexible or ~~ridged~~ rigid separator plate and said flexible membrane electrode assembly;
4. a manifold for the delivery and removal of reactants and reactant products to and from the fuel cell reactive areas where said manifold may be either a single or multiple manifolds; and/or
5. a bond interposed between said manifold and said flexible or ~~ridged~~ rigid separator plate, wherein said bond affixes said manifold to said flexible or ~~ridged~~ rigid separator plate and wherein said bond provides a seal between said manifold and said flexible or ~~ridged~~ rigid separator plate to prevent the release of reactants from the fuel cell.

In one embodiment the membrane electrode assembly has within it incorporated or bonded reactant diffusion layers as a single assembly.

In another embodiment the membrane electrode assembly is independent from the reactant diffusion layers.

In another embodiment in the fuel cell the flexible adhesive bond incorporates a gasket having adhesive on one side, on both sides or on neither side. This gasket material may be comprised of a single one-component material or a composite material composed of two or more components. The gasket material may be formed as a separate component or be formed on the surface of the separator plate or on the membrane electrode assembly.

In another embodiment the adhesive bond is solely an adhesive without the use of a gasket that may either be applied to the separator plate or to the membrane electrode assembly or to both.

In another embodiment of the gasket material may be in the form of a foam composed of a single one-component material or a composite material composed of two or more components with or without an incorporated adhesive.

In another embodiment the adhesive is applied directly to the bipolar separator plate before placing and adhering the membrane electrode assembly to the bipolar separator plate. The adhesive functions as a sealant to confine the reactants and as a fixative for securing the membrane electrode assembly to the separator plate.

In another embodiment the sealing of the gasket is supported by the bending, rolling or crimping of the edge of the flexible or ~~ridged~~ rigid bipolar separator plate.

In another embodiment the sealing of the gasket is supported by the clamping of the edge of the flexible or ~~ridged~~ rigid bipolar separator plate with auxiliary material which causes the same effect of bending, rolling or crimping the edge for the flexible or ~~ridged~~ rigid bipolar separator plate.

In addition, assembled and tested modular cells clearly showed measurable consistency between cells. Even with a hand assembly technique nineteen demonstrated non-leaking cells operating as an ambient air natural convection stack system at 25 mA/cm^2 showed a variation within 5% of the average cell voltage for the stack.

The embodiments of the present invention differ considerably from 6,080,503 in as much as the present invention pertains to a single separator plate bonded to a single membrane electrode assembly as opposed to the conventional art teaching of two separator plates bonded to each side of a single membrane electrode assembly. The manufacturing improvement and increase in efficiency of these components is readily apparent.

BRIEF DESCRIPTION OF THE FIGURES

Figure 1 is a schematic representation of the basic conventional fuel cell process. It shows the extracted hydrogen ions which combine with oxygen across a PEM membrane to produce electrical power.

Figure 2 is a schematic representation of the conventional PEM fuel cell stack of electrodes compressed together with heavy end plates and tie rod bolts.

Figure 3 is a schematic representation of an exploded view of a conventional PEM single cell of a conventional fuel cell assembly.

Figure 4 is a schematic representation of an exploded view of a conventional PEM fuel cell stack of electrodes showing the arrangement of the internal and external parts.

Figures 5A and 5B are a schematic representations of the obverse and reverse integrated and modular bipolar separator plate (BSP), membrane electrode assembly (MEA) and manifold. Figure 5C is a schematic representation of reverse of an integrated and modular bipolar separator plate showing an alternate, vertical, arrangement of the compliant contacts.

Figure 6 is an exploded schematic representation of the integrated and modular fuel cell assembly.

Figures 7A and 7B are detailed schematic representations of the integrated and modular cell assembly showing manifold and MEA attachments.

Figures 8A, 8B, 8C and 8D are schematic representations of the integrated and modular cell components and assembly having a single manifold of the present invention.

Figures 9A, 9B, 9C and 9D are schematic representations of a thin metal bipolar separator plates before (9A) and after (9B) crimping or rolling of the edges to support the MEA. 9C is a detail of the schematic representation of 9A and 9B.

DETAILED DESCRIPTION OF THE INVENTION AND PREFERRED EMBODIMENTS

Definitions

As described herein:

“BSP” refers to bipolar separator plates which term is conventional in the art.

“Flexible” refers to the BSP and/or MEA ability to flex with the forces and pressures of operation. The bonds between the components are substantially leak free. This flexibility assures that electrical contact is maintained by the compliant contacts as referenced in U.S. Serial Number 60/226,471, filed August 18, 2000; and U.S. Serial Number 09/834,390, filed April 13, 2001 (Express Mail No.: EL700013365US).

“Materials of construction” refers to the conventional materials that one of skill in the art would normally select to produce a conventional fuel cell. Unless otherwise noted herein for the present invention, conventional materials of construction are used.

“MEA” refers to the membrane electrode assembly.

“PEM” refers to proton exchange membrane — a component of a MEA and fuel cell.

“Module” refers to identical single interchangeable separable components containing the bipolar separator plate, membrane electrode assembly, separate diffusion layers (if used), gaskets (if used), manifolds adhesives, and seals (if used) and comprises a single electrochemical cell.

As stated above, traditional fuel cell design has relied on the “filter press” type of fabrication and assembly, see Figure 2, i.e., end-plates and tie rods, to create suitable electrical contact between the MEA and adjacent BSP, see Figure

3. In the conventional fuel cell art, all the BSPs and MEAs must be assembled concurrently during the assembly of the fuel cell stack see Figure 4. This assembly method requires that all manifold and membrane sealing as well as electrical contact be accomplished at once when the stack of cells is in final assembly. If there is leakage or poor electrical contact in a single cell, then all the cells of the stack must be disassembled for remediation. While there are other assembly methods used in the fabrication of fuel cell stacks, none use a true modular approach to fuel cell assembly. This is the case for U. S. Patent number 6,080,503 wherein in the conventional art, a single MEA is "adhesively bonded to a pair of separator plates." While the language of this issued patent uses the term "module," these are not true single cell modules. They are better described as one and a half cell subassemblies, which are then combined into a stack and "compressed between two end plates in order to maintain good electrical plate-to-plate contact between two adjacent modules." This is nothing more than preassembling portions of the stack beforehand and then assembling them in the conventional inefficient bulky filter press method.

With reference to Figures 5A, 5B, 5C, 6, 7A and 7B, the present fuel cell design 50 uses a single thin metal plate BSP 61 onto which the MEA 65 and reactant manifolds 51 are assembled into modular units prior to being incorporated into a complete fuel cell unit (stack). These fuel cell modules are comprised of a single BSP 61, which may contain a reactant flow pattern 62, the MEA 65 with or without an incorporated diffusion layer 67, separate diffusion layers if needed, an adhesive 66 or an adhesive backed gasket 64, the reactant manifolds 51 and the manifold seals or adhesives 64A or 66.

Other features in Figures 5A, 5B, 5C, 6, 7A and 7B include on the obverse adhesive or gasket by the hole 52, reactant passageway 53, edge seal 54, inactive border 55 and active membrane 56. Figure 5B in this orientation has improved control of heat

On the reverse side Figure 5B, the features are the same as for Figure 5A and further include the multiple arrays of compliant electrical contacts 69 as described in pending U.S. Application Serial No. 60/226,471. Figure 5C shows an alternate arrangement of the multiple arrays of compliant electrical contacts 69 as described in pending U.S. Application Serial No. 60/226,471.

In the modular cell stack assembly, the manifolds 51 and 51A contact the adjacent manifold of the next modular cell. The compliant electrical contacts 69 contact the active membrane 65 of the adjacent cell.

Conventional fuel cell design is followed up to a certain point. See teachings of U.S. Patent 6,030,718 and other U.S. patents listed on pages 2, 3 and 4 above. As is apparent to those skilled in the art, these incorporated-by-reference U.S. patents disclose the basic design to fabricate a conventional fuel cell. With the text and figures provided herein, those skilled in the art are enabled to fabricate the present invention. In the creation of the single cells integrated modules of the present invention, the following additional methodology is followed:

Conventional fuel cell designs are sealed around the edge of the BSP and the BSP to the MEA by the use of substantially non-adhesive inert gaskets. The pressure from the tie-rods and end-plates holds and seals the assembly in place.

In contrast, the modular design shown in Figures 5A, 5B, 5C, 6, 7A and 7B, utilizes adhesives or gaskets with adhesive seals between the MEA 65 and single BSP 61. Figures 7A and 7B show an adhesive 66, with or without a carrier gasket 64, to bond the MEA 65 to the hydrogen side of the BSP 61. In addition, the reactant manifolds 51 are adhesively bonded 64A to the BSP 61 in a similar manner, as is the MEA 65.

The manifolds 51 are external to the BSP 61 and the MEA 65. The MEA 65 does not have holes for manifold or gas passages. This feature eliminates the

use of the MEA 65 as a through passage and, likewise eliminates any possible leakage due to a through passage through the membrane 67.

This new assembly process creates an integrated, leak proof assembly. Each assembly is leaked tested and performance tested independently from the stack of the individual cells as is conventional in the art.

This novel method of assembly decouples the MEA sealing from the stack assembly, and compressive loads of the end-plates and tie-rods.

The individual components of the integrated and modular BSP/MEA separator plates for fuel cells are mass-produced and assembled into the integrated and modular BSP/MEA and tested independently off-line to increase the assurance that a functional stack of cells will be produced.

Additionally, since each module is an integrated, sealed unit, the stack is assembled and held together more simply than the traditional means of heavy end-plates and tie-rods required to maintain sealing and intimate contact between surfaces to effect electrical conductivity.

The manifold 81 on the integrated, modular BSP/MEA is of a single arrangement as shown in Figures 8A, 8B, 8C and 8D or multiple manifolds of those shown in Figures 5A, 5B, and 5C[.,,]. The manifolds 51A and 51B allow the delivery and exhausting of the reactants and reaction products respectively. In a multiple manifold configuration, Figures 5A, 5B, 5C and 6 the reactants may be delivered on one side by one manifold 51A and the reaction products exhausted on the other side by a different manifold 51B. In the single manifold 81 configuration the reactants may be delivered and exhausted by the single manifold 81.

In order to support the sealing of the gaskets and/or sealing adhesives 64 the edges of the flexible or ~~ridged~~ rigid bipolar separator plate 61 can be bend over or rolled and/or crimped against the sealing service of the membrane

electrode assembly. Figures 9A, 9B, 9C and 9D illustrate a method for achieving this end, shown without the MEA 65, gasket 64 for manifolds 51 for clarity. Figures 9A and 9C show a flexible or ~~ridged~~ rigid bipolar separator plate 61 with extended edges 90, 91 before being rolled or crimped over the sealing edge as shown in Figures 9B and 9D. There are numerous methods for achieving the desired effect of mechanically restraining the edge of the adhesives or gaskets in order to prevent the release of reactants from the fuel cell well known to those trained in the mechanical arts. These methods include the simple bending and crimping or hemming as shown in Figures 9A through 9C but may include rolling the edges, the addition of secondary material such as a band around the periphery of the flexible or ~~ridged~~ rigid bipolar separator plate. In addition, the corners need not be of a squared configuration but may be rounded in order to facilitate the rolling and or crimping of the edge or added material.

Any adhesives or gaskets incorporating adhesives necessarily must form an adequate bond with the bipolar separator plate and the membrane electrode assembly and between the bipolar separator plate and the manifold. Below are a few examples of adhesives, which may be of use in bonding the MEAs and manifolds to the BSPs:

Specific commercial tapes of the 3M Corp. (of St. Paul, Minnesota) family of VHB (Very High Bond) Tapes, such as product number 4920, a closed-cell acrylic foam carrier with adhesive, or F-9469 PC, a adhesive transfer tape (trademarks of the 3M Company of St. Paul Minnesota).

Commercial acrylic adhesives such as Loctite Product 312 or 326 (trademark of the Loctite Corporation of Rocky Hill, Connecticut) or 3M Scotch-Weld Acrylic Adhesive such as DP-805 or DP-820 (trademark of the 3M Company St. Paul Minnesota).

Specific epoxy products such as 3M 1838 (trademark of the 3M Company of St. Paul Minnesota) or Loctite E-20HP. (Trademark of the Loctite Corporation of Rocky Hill, Connecticut.)

These examples are not to imply the only materials applicable to the bonding of the MEAs and the BSPs and the manifolds to the BSPs but only illustrate some of the suitable materials. These materials are applied with the typical methods made use of by those skilled in the art such as hand or robotic placement, hand or robotic dispensing, screen or stencil printing, rolling and spraying.

In one embodiment, 3M Company VHB tape #4920 closed cell acrylic foam with adhesive is used as described herein. This results in well-bonded manifolds to bipolar separator plates and MEAs to BSPs. The resulting fuel cell operates with comparable, better efficiency or significantly better efficiency than those fuel cells, which are conventional in the art.

While only a few embodiments of the invention have been shown and described herein, it will become apparent upon reading this application to those skilled in the art that various modifications and changes can be made to provide a flexible or ~~ridged~~ rigid modular BSP/MEA thin bipolar separator plates and components for fuel cells in a fully functioning fuel cell device without departing from the spirit and scope of the present invention. The present approach to produce a novel fuel cell is applicable to generally any cell geometry or configuration, such as rectangular, square, round or any other planar geometry or configuration. All such modifications and changes coming within the scope of the appended claims are intended to be carried out thereby.

CERTIFICATION UNDER 37 CFR 1.8

I hereby certify that the foregoing:

Appendix to Amendment: Marked up Specification

is being deposited with the United States Postal Service on February 15, 2007
with sufficient postage as first class mail in an envelope addressed to the:
Commissioner for Patents, P.O. Box 1450, Alexandria, VA 22313-1450.
